## Two AMPL Problems for Homework 3

A few years ago I downloaded some data from the National Oceanic and Atmospheric Administration (NOAA):
https://www.ncdc.noaa.gov/cdo-web/datatools
The data is 55 years of daily average temperatures at McGuire Air Force Base, here in balmy NJ:

[^0]

Here's the data in tabular form:

| 1955 | 53.85 | 1965 | 52.13 | 1975 | 54.78 | 1985 | 54.22 | 1995 | 54.11 | 2005 | 53.81 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1956 | 53.21 | 1966 | 52.92 | 1976 | 52.50 | 1986 | 54.53 | 1996 | 53.22 | 2006 | 55.79 |
| 1957 | 53.92 | 1967 | 52.66 | 1977 | 53.21 | 1987 | 54.75 | 1997 | 54.99 | 2007 | 54.04 |
| 1958 | 51.38 | 1968 | 53.23 | 1978 | 52.29 | 1988 | 53.39 | 1998 | 55.18 | 2008 | 54.54 |
| 1959 | 54.26 | 1969 | 53.98 | 1979 | 53.46 | 1989 | 53.35 | 1999 | 54.34 | 2009 | 53.03 |
| 1960 | 52.91 | 1970 | 52.97 | 1980 | 54.17 | 1990 | 56.38 | 2000 | 53.15 |  |  |
| 1961 | 53.08 | 1971 | 54.07 | 1981 | 53.54 | 1991 | 56.19 | 2001 | 57.55 |  |  |
| 1962 | 51.45 | 1972 | 53.34 | 1982 | 53.47 | 1992 | 53.11 | 2002 | 55.94 |  |  |
| 1963 | 51.84 | 1973 | 54.87 | 1983 | 54.68 | 1993 | 54.19 | 2003 | 53.37 |  |  |
| 1964 | 52.81 | 1974 | 53.71 | 1984 | 53.12 | 1994 | 54.10 | 2004 | 53.62 |  |  |

For your convenience, the data can also be download as a plain text file from here:

> http://vanderbei.princeton.edu/307/homework/yearlyTemps.txt

Visually, there appears to be a small upward trend in the average temperatures. Let's try to quantify this trend. To do this, we will try to draw the best straight line through the data:

$$
y=m(x-1955)+b
$$

Here, $x$ is the time variable (in years), $y$ denotes the estimated average temperature, $m$ is the slope, i.e., the upward (or downward) trend, and $b$ is the "intercept" (at year 1955). We have $n=55$ specific data points: $\left(x_{i}, y_{i}\right), i=1,2, \ldots, n$. These data points don't lie exactly on the idealized straight line. Let's denote the deviations by $\varepsilon_{i}$ :

$$
\varepsilon_{i}=y_{i}-\left(m\left(x_{i}-1955\right)+b\right)
$$

Our goal is to minimize the sum of the absolute values of the $\varepsilon_{i}$ 's:

$$
\operatorname{minimize} \sum_{i=1}^{n}\left|\varepsilon_{i}\right| \text {. }
$$

As discussed in the context of the Markowitz model, the absolute values can be handled by introducing new variables, $\alpha_{i} \geq\left|\varepsilon_{i}\right|$, and solving the following linear programming problem:

$$
\operatorname{minimize} \sum_{i=1}^{n} \alpha_{i}
$$

subject to the constraints

$$
\begin{aligned}
\varepsilon_{i} & =y_{i}-\left(m\left(x_{i}-1955\right)+b\right) & & i=1,2, \ldots, n \\
\varepsilon_{i} & \leq \alpha_{i} & & i=1,2, \ldots, n \\
-\alpha_{i} & \leq \varepsilon_{i} & & i=1,2, \ldots, n
\end{aligned}
$$

To summarize, the data for this problem are the $x_{i}$ 's and $y_{i}$ 's and the variables are the slope $m$, the intercept $b$, the deviations $\varepsilon_{i}$ 's, and their absolute values $\alpha_{i}$ 's.

1. Write an Ampl model to solve for these variables. Of course, we are mainly interested in the slope $m$.
(a) What is the slope in degrees Fahrenheit per century?
(b) What is the estimated average temperature for the year 2019 ?
2. Change your Ampl model so that it minimizes the sum of the squares of the $\alpha_{i}$ 's.
(a) What is the slope in degrees Fahrenheit per century?
(b) What is the estimated average temperature for the year 2019 ?

Note: Submit via Blackboard both AMPL models and the answers to the questions above. With the AMPL models provide a step-by-step explanation of what it is doing and how.

[^0]:    Using this raw data, I computed 55 yearly averages:
