

Linear Programming: Chapter 23
Quadratic Programming
The Markowitz Model for Portfolio Optimization

1 What is Quadratic Programming?

Objective is convex quadratic.

$$\text{minimize } c^T x + \frac{1}{2} x^T Q x$$

$$\text{subject to } Ax \geq b$$

Constraints **must be** linear.

$$x \geq 0$$

Without loss of generality, the matrix Q of quadratic coefficients may be assumed symmetric.

The matrix Q must be positive semidefinite. Any of the following conditions characterize positive semidefiniteness:

- $\xi^T Q \xi \geq 0$ for all ξ .
- All eigenvalues of Q are nonnegative.
- There exists a matrix F such that $Q = F^T F$.

Press Release - The Sveriges Riksbank (Bank of Sweden) Prize in Economic Sciences
in Memory of Alfred Nobel

KUNGL. VETENSKAPSAKADEMIEN
THE ROYAL SWEDISH ACADEMY OF SCIENCES

16 October 1990

THIS YEAR'S LAUREATES ARE PIONEERS IN THE THEORY OF FINANCIAL ECONOMICS
AND CORPORATE FINANCE

The Royal Swedish Academy of Sciences has decided to award the 1990 Alfred Nobel Memorial Prize
in Economic Sciences with one third each, to

Professor **Harry Markowitz**, City University of New York, USA,
Professor **Merton Miller**, University of Chicago, USA,
Professor **William Sharpe**, Stanford University, USA,

for their pioneering work in the theory of financial economics.

Harry Markowitz is awarded the Prize for having developed the theory of portfolio choice;
William Sharpe, for his contributions to the theory of price formation for financial assets, the so-called,
Capital Asset Pricing Model (CAPM); and
Merton Miller, for his fundamental contributions to the theory of corporate finance.

Summary

Financial markets serve a key purpose in a modern market economy by allocating productive resources
among various areas of production. It is to a large extent through financial markets that saving in
different sectors of the economy is transferred to firms for investments in buildings and machines.
Financial markets also reflect firms' expected prospects and risks, which implies that risks can be spread
and that savers and investors can acquire valuable information for their investment decisions.

The first pioneering contribution in the field of financial economics was made in the 1950s by Harry
Markowitz who developed a theory for households' and firms' allocation of financial assets under
uncertainty, the so-called theory of portfolio choice. This theory analyzes how wealth can be optimally
invested in assets which differ in regard to their expected return and risk, and thereby also how risks can
be reduced.

1992	1.036	1.079	1.076	1.090	1.174	1.076	0.878	0.926
1993	1.031	1.217	1.100	1.113	1.162	1.110	1.326	1.146
1994	1.045	0.889	1.012	0.999	0.968	0.965	1.078	0.990

3 Risk vs. Reward

Reward—estimated using historical means:

$$\text{reward}_j = \frac{1}{T} \sum_{t=1}^T R_j(t).$$

Risk—estimated using historical variances:

$$\text{risk}_j = \frac{1}{T} \sum_{t=1}^T (R_j(t) - \text{reward}_j)^2.$$

4 Hedging

Investment A: up 20%, down 10%, equally likely.

Investment B: up 20%, down 10%, equally likely.

Correlation: up years for A are down years for B and vice versa.

Portfolio—half in A, half in B: up 5% every year!

5 Portfolios

Fractions: x_j = fraction of portfolio to invest in j .

Portfolio's Historical Returns:

$$R(t) = \sum_j x_j R_j(t)$$

Portfolio's Reward:

$$\text{reward}(x) = \frac{1}{T} \sum_{t=1}^T R(t) = \frac{1}{T} \sum_{t=1}^T \sum_j x_j R_j(t)$$

6 Portfolio's Risk

$$\begin{aligned}\text{risk}(x) &= \frac{1}{T} \sum_{t=1}^T (R(t) - \text{reward}(x))^2 \\ &= \frac{1}{T} \sum_{t=1}^T \left(\sum_j x_j R_j(t) - \frac{1}{T} \sum_{s=1}^T \sum_j x_j R_j(s) \right)^2 \\ &= \frac{1}{T} \sum_{t=1}^T \left(\sum_j x_j \left(R_j(t) - \frac{1}{T} \sum_{s=1}^T R_j(s) \right) \right)^2 \\ &= \frac{1}{T} \sum_{t=1}^T \left(\sum_j x_j (R_j(t) - \text{reward}_j) \right)^2\end{aligned}$$

Note: $\text{risk}(x)$ is quadratic in the x_j 's.

7 The Markowitz Model–The Objective

Decision Variables: the fractions x_j .

Objective: maximize return, minimize risk.

Fundamental Lesson: can't simultaneously optimize two objectives.

Compromise: maximize a combination of reward and risk:

$$\text{reward}(x) - \mu \text{risk}(x)$$

Parameter μ is called risk aversion parameter.

$$0 \leq \mu < \infty$$

Large value for μ puts emphasis on risk minimization.

Small value for μ puts emphasis on reward maximization.

8 The Markowitz Model–The Constraints

Constraints:

$$\sum_j x_j = 1$$
$$x_j \geq 0 \quad \text{for all investments } j$$

Quadratic Program:

Constraints are linear.

Objective is quadratic.

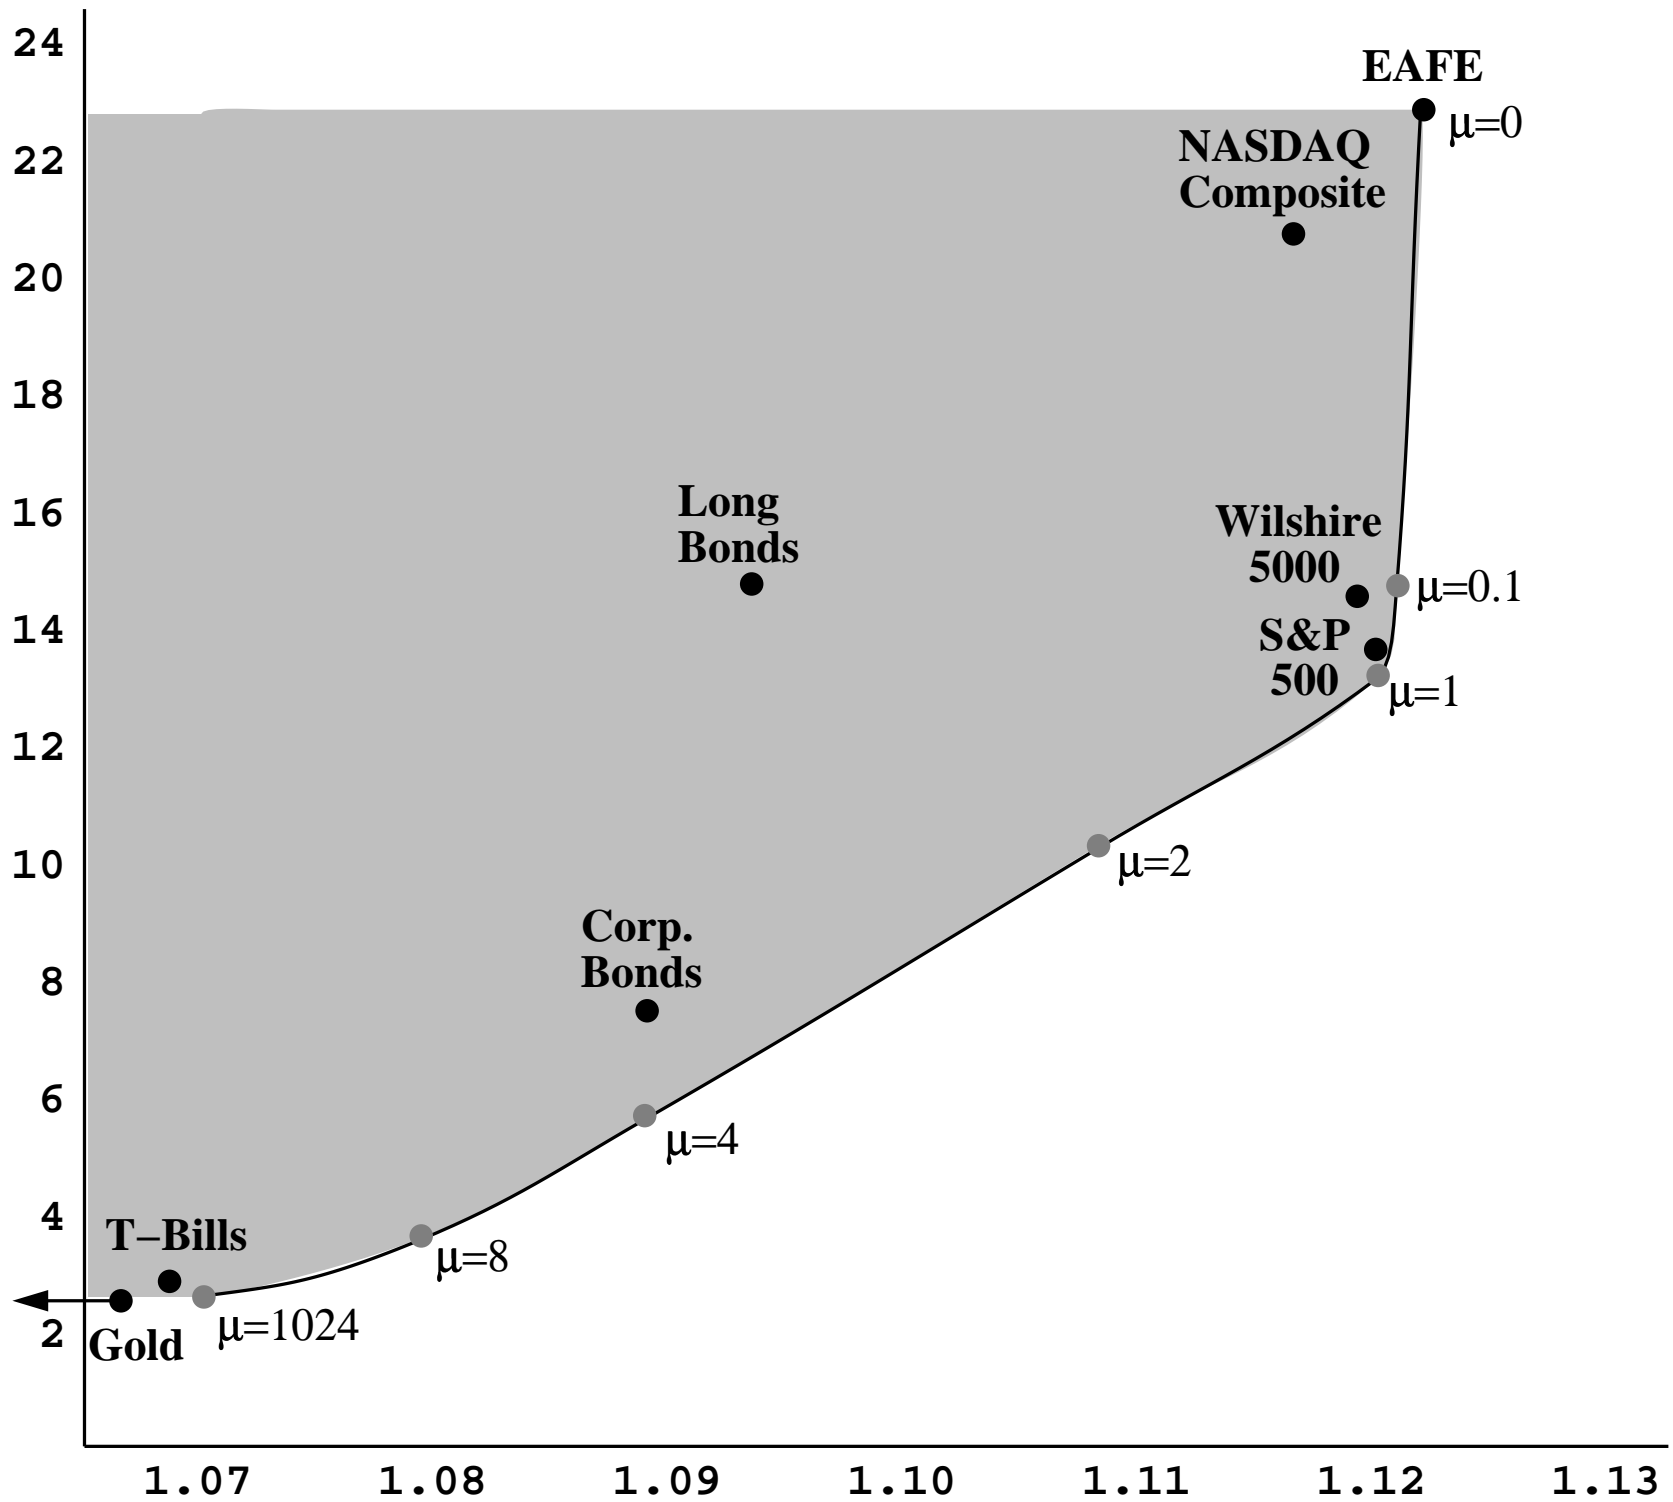

9 Efficient Frontier

Varying μ produces the so-called **efficient frontier**.

Portfolios on the efficient frontier are reasonable.

Portfolios not on the efficient frontier can be strictly improved.

μ	Gold	US 3-Month T-Bills	Lehman Bros. Corp. Bonds	NASDAQ Composite	S&P 500	EAFE	Mean	Std. Dev.

11 Interior-Point Methods for Quadratic Programming

Start with an optimization problem—in this case QP:

$$\begin{aligned} \text{minimize} \quad & c^T x + \frac{1}{2} x^T Q x \\ \text{subject to} \quad & Ax \geq b \\ & x \geq 0 \end{aligned}$$

Use slack variables to make all inequality constraints into nonnegativities:

$$\begin{aligned} \text{minimize} \quad & c^T x + \frac{1}{2} x^T Q x \\ \text{subject to} \quad & Ax - w = b \\ & x, w \geq 0 \end{aligned}$$

Replace nonnegativity constraints with **logarithmic barrier terms** in the objective:

$$\begin{aligned} \text{minimize} \quad & c^T x + \frac{1}{2} x^T Q x - \mu \sum_j \log x_j - \mu \sum_i \log w_i \\ \text{subject to} \quad & Ax - w = b \end{aligned}$$

Introduce **Lagrange multipliers** to form **Lagrangian**:

$$c^T x + \frac{1}{2} x^T Q x - \mu \sum_j \log x_j - \mu \sum_i \log w_i - y^T (Ax - w - b)$$

Set derivatives to zero:

$$\begin{aligned} c + Qx - \mu X^{-1} e - A^T y &= 0 \\ -\mu W^{-1} e + y &= 0 \\ -Ax + w + b &= 0 \end{aligned}$$

Introduce **dual complementary variables**:

$$z = \mu X^{-1} e$$

Rewrite system:

$$c + Qx - z - A^T y = 0$$

$$XZe = \mu e$$

$$WYe = \mu e$$

$$b - Ax + w = 0$$

Introduce **step directions**: Δx , Δy , Δw , Δz .

Write the above equations for $x + \Delta x$, $y + \Delta y$, $w + \Delta w$, and $z + \Delta z$:

$$c + Q(x + \Delta x) - (z + \Delta z) - A^T(y + \Delta y) = 0$$

$$(X + \Delta X)(Z + \Delta Z)e = \mu e$$

$$(W + \Delta W)(Y + \Delta Y)e = \mu e$$

$$b - A(x + \Delta x) + (w + \Delta w) = 0$$

Rearrange with “delta” variables on left and drop nonlinear terms on left:

$$Q\Delta x - \Delta z - A^T \Delta y = -c - Qx + z + A^T y$$

$$Z\Delta x + X\Delta z = \mu e - ZXe$$

$$W\Delta y + Y\Delta w = \mu e - WYe$$

$$-A\Delta x + \Delta w = -b + Ax - w$$

This is a **linear** system of $2m + 2n$ equations in $2m + 2n$ unknowns.

Solve'em.

Yadda, yadda, yadda.

12 Parting Comments

The matrix Q must be **positive semidefinite** (psd), which means that all of the eigenvalues of Q must be nonnegative.

Such QPs are called **convex quadratic programming problems**.

Nonconvex QPs are as hard to solve as integer programs. Many local optima, which is best? Hmmm.

The Markowitz model is a convex QP (the covariance matrix is always psd).
