Pupil Mapping

Advantages:

- 100% throughput
- Implicit magnification... effectively $iwa \approx 1\lambda/D$.

Disadvantages:

- Diffraction effects limit achievable contrast to 10^{-5} for a pure pupil-mapping system.

$$R(\tilde{r}) = \pm \sqrt{\int_0^{\tilde{r}} 2A^2(s) ds}.$$

$$\frac{\partial h}{\partial r}(r) = \frac{r - \tilde{R}(r)}{\sqrt{Q_0^2 + (n^2 - 1)(r - \tilde{R}(r))^2}}$$

$$\frac{\partial \tilde{h}}{\partial \tilde{r}}(\tilde{r}) = \frac{R(\tilde{r}) - \tilde{r}}{\sqrt{Q_0^2 + (n^2 - 1)(R(\tilde{r}) - \tilde{r})^2}}$$

n is the refractive index and

$$\begin{aligned} Q_0 &= -(n - 1)z \\ &= S(R(\tilde{r}), \tilde{r}) + n(\tilde{h}(\tilde{r}) - h(R(\tilde{r}))) \end{aligned}$$

Notes:

- the second expression for Q_0 is in fact independent of \tilde{r} .
- for mirrors, put $n = -1$.

Huygens Wavelets

Cartesian Coordinates

$$E_{\text{out}}(\tilde{x}, \tilde{y}) = \iint \frac{1}{\lambda Q(\tilde{x}, \tilde{y}, x, y)} e^{2\pi i Q(\tilde{x}, \tilde{y}, x, y)/\lambda} dy dx,$$

where Q denotes the optical path length:

$$Q(\tilde{x}, \tilde{y}, x, y) = \sqrt{(x - \tilde{x})^2 + (y - \tilde{y})^2 + (h(r) - \tilde{h}(\tilde{r}))^2} + n(Z - h(r) + \tilde{h}(\tilde{r}))$$

Polar Coordinates

$$E_{\text{out}}(\tilde{r}) = \iint \frac{1}{\lambda Q(\tilde{r}, r, \theta)} e^{2\pi i Q(\tilde{r}, r, \theta)/\lambda} r d\theta dr,$$

where

$$Q(\tilde{r}, r, \theta) = \sqrt{r^2 - 2r\tilde{r} \cos \theta + \tilde{r}^2 + (h(r) - \tilde{h}(\tilde{r}))^2} + n(Z - h(r) + \tilde{h}(\tilde{r})).$$

Double integrals are hard!

[Home Page](#)[Title Page](#)[Contents](#)[Page 7 of 21](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

Fresnel Approximation

Assuming a *large separation* between the lenses and that the lenses are themselves *thin*, we get

$$\sqrt{r^2 - 2r\tilde{r} \cos \theta + \tilde{r}^2 + (h(r) - \tilde{h}(\tilde{r}))^2} \\ \approx (h(r) - \tilde{h}(\tilde{r})) + \frac{r^2 - 2r\tilde{r} \cos \theta + \tilde{r}^2}{2z}.$$

Fresnel uses this approximation in the exponential (and the “paraxial” approximation in the leading factor) to get the *standard Fresnel approximation*:

$$E_{\text{out}}(\tilde{r}) = \frac{2\pi}{\lambda Z} e^{\pi i \frac{\tilde{r}^2}{z\lambda} + 2\pi i \frac{(n-1)\tilde{h}(\tilde{r})}{\lambda}} \int e^{\pi i \frac{r^2}{z\lambda} - 2\pi i \frac{(n-1)h(r)}{\lambda}} J_0(2\pi r\tilde{r}/z\lambda) r dr.$$

$n = 1.5$. $D = 25\text{mm}$. $z = 15D$. $\lambda = 632.8\text{nm}$.

Galilean Telescope: $A \equiv a$

$$R(\tilde{r}) = a\tilde{r} \quad \tilde{R}(r) = r/a$$

$$h(r) = z + \frac{\sqrt{Q_0^2 + (n^2 - 1)(1 - 1/a)^2 r^2} - |Q_0|}{(n^2 - 1)(1 - 1/a)}$$

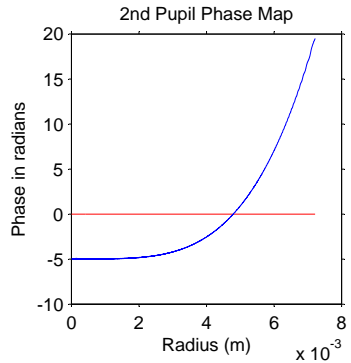

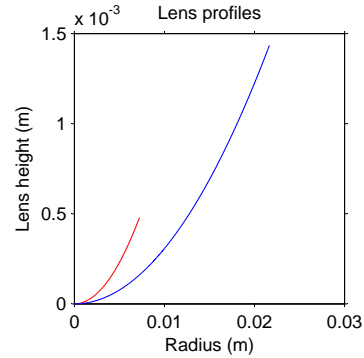

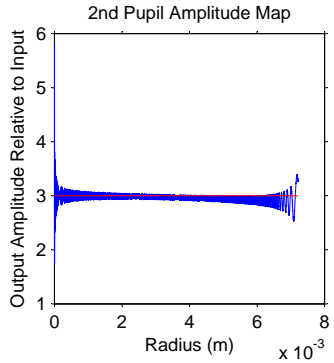

$$\tilde{h}(\tilde{r}) = \frac{\sqrt{Q_0^2 + (n^2 - 1)(a - 1)^2 \tilde{r}^2} - |Q_0|}{(n^2 - 1)(a - 1)}$$

If $n > 1$, then both lenses are hyperbolic.

If $n < 1$, then both lenses are elliptical.

Fresnel approximation is *very bad*.

Better Than Fresnel (BTF)

We retain the paraxial approximation for the leading factor.

We can subtract an arbitrary constant from the Q in the exponent.

Let's choose to subtract $Q(\tilde{r}, R(\tilde{r}), 0)$. We compute:

$$\begin{aligned} Q(\tilde{r}, r, \theta) - Q(\tilde{r}, R(\tilde{r}), 0) &= S(\tilde{r}, r, \theta) - S(\tilde{r}, R(\tilde{r}), 0) + n(h(R(\tilde{r})) - h(r)) \\ &= \frac{S^2(\tilde{r}, r, \theta) - S^2(\tilde{r}, R(\tilde{r}), 0)}{S(\tilde{r}, r, \theta) + S(\tilde{r}, R(\tilde{r}), 0)} + n(h(R(\tilde{r})) - h(r)) \end{aligned}$$

Then, we simplify the numerator:

$$\begin{aligned} S^2(\tilde{r}, r, \theta) - S^2(\tilde{r}, R(\tilde{r}), 0) &= (r - R(\tilde{r}))(r + R(\tilde{r})) - 2\tilde{r}(r \cos \theta - R(\tilde{r})) \\ &\quad + (h(r) - h(R(\tilde{r}))) (h(r) + h(R(\tilde{r})) - 2\tilde{h}(\tilde{r})). \end{aligned}$$

Page 12 of 21

[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

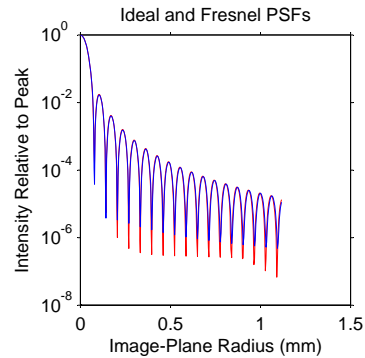

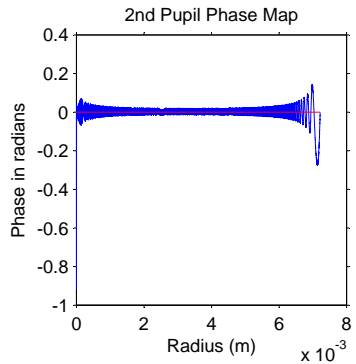

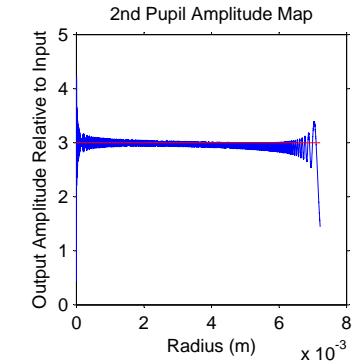

Mo' Better

So far, everything is exact (except for the paraxial approximation). The only other approximation is to replace $S(\tilde{r}, r, \theta)$ in the denominator with $S(\tilde{r}, R(\tilde{r}), 0)$ so that the denominator becomes just $2S(\tilde{r}, R(\tilde{r}), 0)$. Replacing the integral on θ with the appropriate Bessel function, we get a new approximation:

$$E_{\text{out}}(\tilde{r}) \approx \frac{2\pi}{\lambda Z} \int e^{2\pi i \left(\frac{r^2 - R(\tilde{r})^2 + 2\tilde{r}R(\tilde{r}) + (h(r) - h(R(\tilde{r}))) (h(r) + h(R(\tilde{r})) - 2\tilde{h}(\tilde{r}))}{2S(\tilde{r}, R(\tilde{r}), 0)\lambda} + \frac{n}{\lambda} (h(R(\tilde{r})) - h(r)) \right)} \cdot J_0 \left(\frac{2\pi \tilde{r} r}{\lambda S(\tilde{r}, R(\tilde{r}), 0)} \right) r dr.$$

[Home Page](#)[Title Page](#)[Contents](#)[Page 13 of 21](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

Example: $A \equiv 3$

This approximation is much better than Fresnel.
